## ABSTRACT

Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is developed as a high-temperature NO<sub>x</sub> storage and reduction (NSR) catalyst. K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>, in place of alkali metals and γ-Al<sub>2</sub>O<sub>3</sub>, works as both support and NO<sub>x</sub> adsorber; and, unlike alkali-doped NSR catalysts that tend to deactivate at temperature higher than 500 °C, K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> shows stable NO<sub>x</sub> adsorption in a high temperature range of 500–600 °C. The NO<sub>x</sub> storage and reduction performance over Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is studied by various means, including temperature-programmed adsorption, isothermal storage, and lean-rich cycling experiments. A maximum value of adsorbed NO<sub>x</sub> species (close to 1.2 mmol/g catalyst) is achieved at 550 °C. Temperature-programmed de-sorption reveals that the adsorbed NO<sub>x</sub> on Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is highly stable, with a peak at 720 °C. Thermal stability investigations indicate Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> has a much higher stability than Pt-K/TiO<sub>2</sub>. Mechanism studies reveal that KNO<sub>3</sub>-like compound is formed after NO<sub>x</sub> adsorption, and that NO<sub>x</sub> storage and reduction process on K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is accompanied by a structure transformation between K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> and K<sub>2</sub>Ti<sub>6</sub>O<sub>13</sub>.

## 1. Introduction

Conventional three-way catalysts (TWCs) are highly efficient in reducing nitrogen oxide (NO<sub>x</sub>), CO, and unburned hydrocarbon (HC) emissions from gasoline engines, which work at stoichiometric air/fuel ratio (A/F = 14.7) [1,2]; however, the general demand for reduced CO<sub>2</sub> emissions and the requirement of more fuel-efficient gasoline engines has led to the development of lean-burn engines that operate at a significantly higher air/fuel ratio (A/F > 14.7) [3–5]. Lean-burn engines run under conditions in which the exhaust gas contains percentage levels of O<sub>2</sub> and the reduction of NO<sub>x</sub> emissions on a TWC falls to very low levels. The reduction of NO<sub>x</sub> under lean operating conditions is perhaps the greatest challenge in this field [6].

A promising approach for NO<sub>x</sub> removal under lean conditions is based on the NO<sub>x</sub> storage-reduction (NSR) concept [7,8]. NSR catalytic systems are operated under alternating lean and rich conditions: NO<sub>x</sub> is stored on the catalyst under lean conditions and subsequently converted to nitrogen by unburned hydrocarbons under rich conditions. A typical NSR catalyst consists of a high-surface-area support (e.g., γ-Al<sub>2</sub>O<sub>3</sub>), an NO<sub>x</sub>-storage component (alkaline or earth alkaline metal oxide), and a noble metal (e.g., Pt)

for both the oxidation of NO and hydrocarbons and the reduction of stored NO<sub>x</sub> [9–15]. The most popular and classical NSR catalyst is Pt-Ba/γ-Al<sub>2</sub>O<sub>3</sub>, as developed by Toyota [16–18]; however, although many experimental studies have investigated the Pt-Ba/γ-Al<sub>2</sub>O<sub>3</sub> catalyst and theoretical models have been developed for this reaction, catalyst deactivations – especially thermal deterioration and sulfur poisoning – have hindered its commercial application [6,7,19–22].

It is well known that such alkali-doped NSR catalysts are mainly operated within the temperature range of 200–400 °C, as their capacities above 400 °C are limited by the NO<sub>x</sub> storage amount [20,23,24]. Therefore, high-temperature (500–600 °C) NO<sub>x</sub> abatement technology represents an important challenge. For high-speed motor vehicles with lean-burn gasoline engines, the exhaust temperature can exceed 600 °C [24]. The reactions that occur between NO<sub>x</sub> storage compound and support at high temperatures (e.g., BaO + Al<sub>2</sub>O<sub>3</sub> → BaAl<sub>2</sub>O<sub>4</sub>) mean that there are few reports on high-temperature NSR catalysts. To the best of our knowledge, only Takahashi et al. [24] have reported a catalyst Pt-K/MgAl<sub>2</sub>O<sub>4</sub> with enhanced NO<sub>x</sub> storage capacity at high temperature; however, this remains an alkali-doped NSR catalyst limited by problems with thermal stability and sulfur poisoning.

Although K has superior NO<sub>x</sub> storage capacity and TiO<sub>2</sub> is relatively resistant to SO<sub>2</sub> poisoning, the solid reaction between them, which forms potassium titanates, has hindered research into the application of both K and TiO<sub>2</sub> as NSR catalysts [25–27]. Potassium titanates are mainly used as photo-catalyst, ion-

**Table 1**

Procedures and corresponding testing conditions used in the present work.

Procedures	Testing conditions
Temperature-programmed adsorption	900 ppm NO + 10% O <sub>2</sub> (or 900 ppm NO <sub>2</sub> ) in He, 200 ml/min, temperature 0–600 °C, 2 °C/min, GHSV 30,000 h <sup>−1</sup>
Isothermal adsorption	430 ppm NO (or 700 ppm NO <sub>2</sub> ), 10% O <sub>2</sub> in He, 200 ml/min, temperature 550 °C or 350 °C, GHSV 15,000 h <sup>−1</sup>
Lean–rich cycling tests	Lean: 400 ppm NO, 5% O <sub>2</sub> in He, 200 ml/min, 5 min per cycle, GHSV 15,000 h <sup>−1</sup> Rich: 400 ppm NO, 3.5% H <sub>2</sub> in He, 200 ml/min, 1 min per cycle, GHSV 15,000 h <sup>−1</sup>
Temperature-programmed de-sorption	460 ppm NO, 200 ml/min He, temperature 0–800 °C, 10 °C/min, GHSV 90,000 h <sup>−1</sup>
Thermal aging	Procedure one: 10% O <sub>2</sub> or 3.5% H <sub>2</sub> , 200 ml/min, temperature 700 °C, GHSV 15,000 h <sup>−1</sup> Procedure two: the gas compositions of lean and rich phases are same to those used in cycling tests, lean 5 min, rich 1 min, 700 °C, 5 h, GHSV 15,000 h <sup>−1</sup>

exchanger, host materials for intercalation of organic compounds, fuel cell electrolytes, advanced reinforcing materials for brakes and so on; their activities in terms of NO<sub>x</sub> storage have yet to be considered in detail [28–33].

Our investigation surprisingly revealed that K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> possesses NO<sub>x</sub> storage capacity at 500–600 °C; on this basis, we developed a novel high-temperature NSR catalyst, Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>. The present work reports on detailed investigations into the synthesis method, structure characterization, activity performance, and mechanism of NO<sub>x</sub> storage on Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>.

## 2. Experimental

### 2.1. Catalyst preparation and characterization

K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> was synthesized by a solid state reaction method [34,35]. Briefly, 13.82 g K<sub>2</sub>CO<sub>3</sub> (Yakuri Pure Chemical Co., Ltd) and 7.99 g TiO<sub>2</sub> (Hombikat UV 100), and proper amount of water were perfectly mixed by ball milling for 24 h, followed by drying in oven overnight. After crushing to fine powders, the sample was calcined at 850 °C for 10 h in air to obtain K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>. Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> with various Pt loadings (1–4 wt.%) was prepared by incipient wetness impregnation with H<sub>2</sub>PtCl<sub>6</sub>·5.7H<sub>2</sub>O (Kojima Chemicals Co., Ltd) as precursor on K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> support. The as-prepared samples were dried in an oven overnight and calcined at 850 °C for 10 h. In this work, the Pt loading of Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is always 2 wt.%, except noted otherwise. For comparison, 2wt.%Pt–20wt.%Ba/γ-Al<sub>2</sub>O<sub>3</sub> and 2 wt.% Pt–K/TiO<sub>2</sub> (K/Ti = 0.5 or 1) were also prepared by a procedure similar to previous reports [36,37]. In brief, Pt was first supported on γ-Al<sub>2</sub>O<sub>3</sub> (Merck KGaA) or TiO<sub>2</sub> (Hombikat UV 100) by incipient wetness impregnation from H<sub>2</sub>PtCl<sub>6</sub>·5.7H<sub>2</sub>O precursor, followed by calcination at 500 °C for 5 h; then Ba or K were added using aqueous solution of barium acetate (Sigma–Aldrich, Inc.) or potassium acetate (Sigma–Aldrich, Inc.) and the obtained samples were further calcined at 500 °C for 5 h.

To evaluate the formations of synthesized K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> and Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>, and further check their structure changes during NO<sub>x</sub> adsorption and reduction, X-ray diffraction patterns were obtained using an X-ray analyzer (XRD, M18XHF, Mac Science Co., Ltd, Yokohama, Japan). Ni-filtered Cu Kα radiation (λ = 1.5415 Å) was used with an X-ray gun operated at 40 kV and 200 mA. Diffraction patterns were obtained within the range of 2θ = 5–70° with a step size of 0.02°. The morphologies of catalysts were investigated by field emission scanning electron microscopy (FE-SEM, Hitachi, S-4200); chemical compositions were determined by energy dispersive X-ray (EDX) analysis. For EDX point analysis, the beam utilized in this work was 100 nm in size; and the corresponding diameter of the analyzing spot was around 1 μm. Fourier transform infrared spectrometer (FT-IR) experiments were performed using a Perkin-Elmer 2000 FT-IR spectrophotometer to

check the adsorbed NO<sub>x</sub> species. A self-supporting thin disc of 13 mm in diameter was prepared by pressing 1 mg catalyst powder and 14 mg KBr (FT-IR grade, Aldrich Chem. Co.) using a manual hydraulic press. All spectra were measured with 4 cm<sup>−1</sup> resolution.

### 2.2. Measurements of catalytic activity and aging

Catalytic tests were performed in a quartz flow reactor (10 mm internal diameter) for which the set-up has been described previously [34,35]. For monitoring the feed compositions and reaction products, an on-line quadrupole mass spectrometer (Balzers Pfeiffer, USA) was used during the lean–rich cycling tests, and an NO<sub>x</sub> analyzer (Chemiluminescence NO–NO<sub>2</sub>–NO<sub>x</sub> analyzer, Model 42C, high level, Thermo Environmental Instruments, Inc.) was used during the temperature-programmed NO<sub>x</sub> adsorption and isothermal NO<sub>x</sub> adsorption tests. Temperature-programmed NO<sub>x</sub> de-sorption (TPD) was utilized to evaluate the stability of the stored NO<sub>x</sub> on the catalysts. The catalysts were first exposed to lean conditions in the cycling test (see Table 1) to attain saturated NO<sub>x</sub> storages at the optimum temperatures. Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> was placed at 550 °C, while Pt–Ba/γ-Al<sub>2</sub>O<sub>3</sub> and Pt–K/TiO<sub>2</sub> were placed at 350 °C. The NO<sub>x</sub>-saturated catalysts were then heated under the same lean gas flow from room temperature to 800 °C with an increase rate of 10 °C/min; and the NO<sub>x</sub> concentration was evaluated by means of the chemiluminescence NO<sub>x</sub> analyzer. Since the inlet gas contained 460 ppm NO, the NO<sub>x</sub> concentration in excess of 460 ppm was quantified as NO<sub>x</sub> desorbed from the catalysts. To assess thermal stability, two thermal aging procedures were used in this study. The first one is aging Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> at 700 °C in oxidative condition (10% O<sub>2</sub>) for 70 h or 200 h, or reductive condition (3.5% H<sub>2</sub>) for 5 h, then testing by temperature-programmed adsorptions. The second is aging Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> at 700 °C in lean and rich fluctuating conditions for 5 h. The 5 min lean and 1 min rich atmospheres were alternatively switched during the entire thermal aging. After that, its performance was evaluated by a lean–rich cycling test at 550 °C. Table 1 summarizes the procedures and testing conditions used in the present work. For the isothermal NO<sub>x</sub> adsorption tests, the difference in the inlet NO and NO<sub>2</sub> concentrations was due to the limitations of our testing system. Although the vehicle emission gases also contain other reductive agents including CO and hydrocarbons, this work only studied the reduction of the adsorbed NO<sub>x</sub> with H<sub>2</sub>.

## 3. Results and discussion

### 3.1. Characterization of catalyst

The XRD patterns of fresh Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> and fresh K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> were analyzed and compared in Fig. 1, from which the characteristic

**Fig. 1.** XRD patterns of (A) fresh  $\text{K}_2\text{Ti}_2\text{O}_5$ , (B) fresh  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ , and (C) reduced  $\text{K}_2\text{Ti}_2\text{O}_5$ , ( $\blacklozenge$ ) Pt.

peaks of Pt are clearly observed at  $39.8^\circ$ ,  $46.4^\circ$  and  $67.7^\circ$ , respectively. The other peaks of these two patterns show a close match with each other, indicating that  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  catalyst consisted of Pt loading on  $\text{K}_2\text{Ti}_2\text{O}_5$  support. For the conventional alkali-doped NSR catalysts, the  $\text{NO}_x$  storage compound is normally doped on support; and the reactions between these two compounds ( $\text{NO}_x$  adsorber and support) are intently to be prevented for a higher  $\text{NO}_x$  storage capacity. However, in the present work, XRD analyses indicate that potassium has completely reacted with  $\text{TiO}_2$  to form a pure  $\text{K}_2\text{Ti}_2\text{O}_5$ ; and no doped potassium species could be found in the synthesized  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ . After treatment in a reductive condition ( $3.5\% \text{H}_2$ ) at  $700^\circ\text{C}$  for 2 h, the structure of  $\text{K}_2\text{Ti}_2\text{O}_5$  kept unchanged (see Fig. 1). It indicates that  $\text{K}_2\text{Ti}_2\text{O}_5$  is stable in both oxidative and reductive conditions. The morphology of fresh  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  was investigated by SEM (Fig. 2). Irregular shaped  $\text{K}_2\text{Ti}_2\text{O}_5$  particles with size ranging from several micro-meters to several-tenth micro-meters were observed. And the white particles assigned to Pt by EDX analysis are clearly observed on the surface of  $\text{K}_2\text{Ti}_2\text{O}_5$  support.

### 3.2. $\text{NO}_x$ adsorption and de-sorption

$\text{NO}_x$  storage on fresh  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  was first studied by temperature-programmed adsorptions with  $\text{NO} + \text{O}_2$ . The effluent  $\text{NO}_x$

**Fig. 2.** SEM image of fresh  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ .

**Fig. 3.**  $\text{NO} + \text{O}_2$  or  $\text{NO}_2$  adsorptions over fresh 1–4 wt.%  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  and fresh 2 wt.%  $\text{Pt}-\text{K}/\text{TiO}_2$  ( $\text{K}/\text{Ti} = 1$ ) during temperature-programmed adsorptions.

concentrations are shown in Fig. 3. Unlike other alkali-doped catalysts, which adsorb  $\text{NO}_x$  at low temperatures,  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  adsorbed  $\text{NO}_x$  at high temperatures ( $500\text{--}600^\circ\text{C}$ ). As we disclosed in the following Section 3.5, the mechanism of  $\text{NO}_x$  storage on  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  could be explained by a structure change from  $\text{K}_2\text{Ti}_2\text{O}_5$  to  $\text{K}_2\text{Ti}_6\text{O}_{13}$ , with the formation of  $\text{KNO}_3$ -like compound. To initial this reaction, a relatively high temperature is required, which explains the reason why  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  could not store  $\text{NO}_x$  at low temperature (e.g.,  $<400^\circ\text{C}$ ). For comparison, the temperature-programmed  $\text{NO} + \text{O}_2$  adsorption on fresh 2 wt.%  $\text{Pt}-\text{K}/\text{TiO}_2$  ( $\text{K}/\text{Ti} = 1$ ) was also carried out (Fig. 3). To prevent the reaction between K and  $\text{TiO}_2$ , a much lower calcination temperature ( $500^\circ\text{C}$ ) was used for this catalyst. Unlike  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ , it adsorbs  $\text{NO}_x$  in a much wider temperature range ( $300\text{--}550^\circ\text{C}$ ).

The  $\text{NO}_x$  adsorption rate increased with increasing Pt loading, and was further greatly increased with  $\text{NO}_2$  feed compared with  $\text{NO} + \text{O}_2$  feed. Based on these results, it seems that  $\text{NO}$  oxidation to  $\text{NO}_2$  is the limiting step of  $\text{NO}_x$  storage for  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ . Whereas, for the conventional NSR catalysts, the high-temperature  $\text{NO}_x$  storage is dependent on not only the  $\text{NO}$  oxidation, but also the stability of adsorbed  $\text{NO}_x$  species; since it tends to decompose at high temperature. In the following part, we have proved that the  $\text{NO}_x$  species adsorbed on  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  is highly stable at  $550^\circ\text{C}$ .

$\text{NO}_x$  storage amount on fresh 2 wt.%  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  (0.6 g) was investigated by the isothermal storage of  $\text{NO} + \text{O}_2$  at  $350^\circ\text{C}$  and  $550^\circ\text{C}$ , respectively, as shown in Fig. 4. As we expected from Fig. 3,

**Fig. 4.** Isothermal  $\text{NO}_x$  storages over fresh 2 wt.%  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  at  $350^\circ\text{C}$  or  $550^\circ\text{C}$ , and fresh  $\text{Pt}-\text{K}/\text{TiO}_2$  ( $\text{K}/\text{Ti} = 1$ ) at  $550^\circ\text{C}$ .

Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> has negligible NO<sub>x</sub> storage at 350 °C. The inset of Fig. 4 clearly shows a rapid saturation of NO<sub>x</sub> storage over Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> at 350 °C. However, at high temperature, after switching to lean conditions, the outlet NO<sub>x</sub> concentration showed a sharp decrease followed by a gradual increase. The difference between inlet and outlet NO<sub>x</sub> concentrations corresponded to the NO<sub>x</sub> stored on the catalyst. It took more than 1000 min for Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> to become saturated. Upon calculation, a maximum value of adsorbed NO<sub>x</sub> species close to 1.2 mmol/g catalyst was achieved, even higher than that of Pt-Ba/γ-Al<sub>2</sub>O<sub>3</sub> (0.8 mmol/g) adsorbed at low temperature (350 °C) [38,39]. The consumed potassium corresponds to around 24% of total potassium in K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>. The isothermal NO<sub>x</sub> storage over fresh Pt-K/TiO<sub>2</sub> (K/Ti = 1) at 550 °C was also tested, which shows a quite different pattern. The NO<sub>x</sub> adsorption rate is very high, and it almost saturated after around 120 min. Its maximum NO<sub>x</sub> storage value is only around 0.45 mmol/g, much lower than that of Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> (1.2 mmol/g). At high temperature, the NO<sub>x</sub> storage properties are highly dependent on the stability of adsorbed NO<sub>x</sub> species and the thermal stability of NO<sub>x</sub> storage compounds. For Pt-Ba/γ-Al<sub>2</sub>O<sub>3</sub> or Pt-K/TiO<sub>2</sub>, a reaction between Ba (or K) and γ-Al<sub>2</sub>O<sub>3</sub> (or TiO<sub>2</sub>) happens at temperature higher than 550 °C, causing a decreased NO<sub>x</sub> storage amount. Consequently, a high temperature is normally intently prevented during operation. However, Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> obtained at 850 °C is much more thermally stable.

Fig. 5 shows the TPD spectra obtained from NO<sub>x</sub>-saturated fresh 2wt.%Pt–20wt.%Ba/γ-Al<sub>2</sub>O<sub>3</sub>, 2 wt.% Pt-K/TiO<sub>2</sub> (K/Ti = 1) and Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>. It is clear that the de-sorption temperature for Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> ( $T_p$  = 720 °C) is much higher than those for 2wt.%Pt–20wt.%Ba/γ-Al<sub>2</sub>O<sub>3</sub> ( $T_p$  = 510 °C) and 2 wt.% Pt-K/TiO<sub>2</sub> (K/Ti = 1) (640 °C). Basing on our calculation by integrating the profiles, the NO<sub>x</sub> de-sorption amount on Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is around 1.35 times of the value on 2wt.%Pt–20wt.%Ba/γ-Al<sub>2</sub>O<sub>3</sub>. This value is very close to the ratio calculated from the maximum NO<sub>x</sub> storage amounts on Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> and 2wt.%Pt–20wt.%Ba/γ-Al<sub>2</sub>O<sub>3</sub> (1.5). 2 wt.% Pt-K/TiO<sub>2</sub> (K/Ti = 1) shows a similar NO<sub>x</sub> storage capacity with Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>. Takahashi et al. [24] and Park et al. [40] reported even much lower de-sorption temperatures for Pt-K/γ-Al<sub>2</sub>O<sub>3</sub> ( $T_p$  = 380 °C) and K/γ-Al<sub>2</sub>O<sub>3</sub> ( $T_p$  = 400 °C). These data indicate that the stability of the adsorbed NO<sub>x</sub> on Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> is much higher than those on alkali-doped NSR catalysts, thereby explaining its high-temperature NO<sub>x</sub> storage performance. The essential reason for such enhanced stability is still not clear to us, and further investigation is needed to reveal it. According to the NO<sub>x</sub> storage mechanism presented in Section 3.5, the KNO<sub>3</sub>-like compound

Fig. 5. Evolution of NO<sub>x</sub> during temperature-programmed de-sorption of NO<sub>x</sub> saturated fresh 2wt.%Pt–20wt.%Ba/γ-Al<sub>2</sub>O<sub>3</sub>, 2 wt.% Pt-K/TiO<sub>2</sub> (K/Ti = 1), and 2 wt.% Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>.

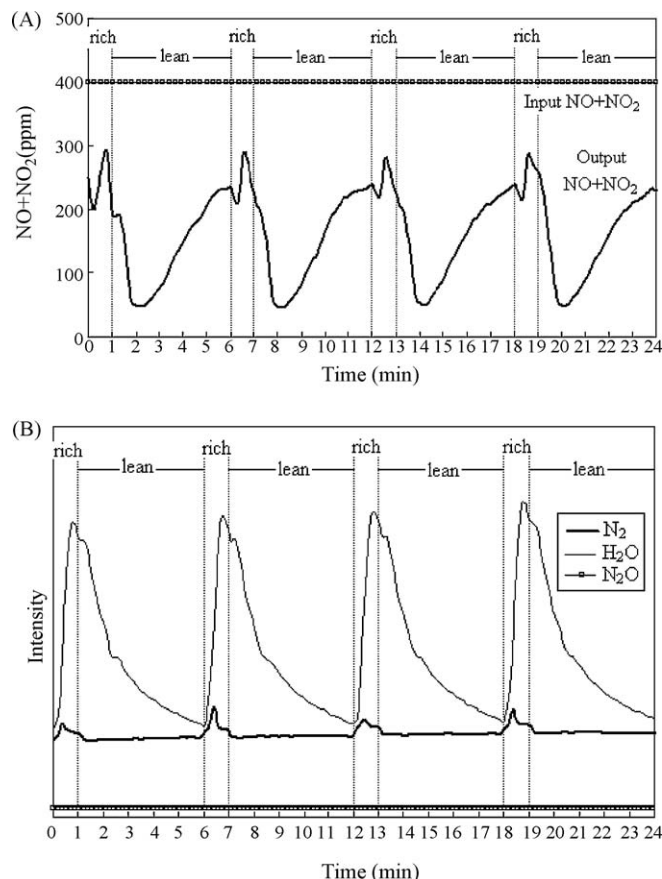

Fig. 6. (A) Evolution of effluent NO + NO<sub>2</sub> during lean–rich cycling test over fresh 2 wt.% Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> at 550 °C. seems formed inside the inter-layers of Ti<sub>2</sub>O<sub>5</sub><sup>2−</sup>. The structure of such formed KNO<sub>3</sub>-like compound might be different from that on support surface, or it might be trapped by other atoms surrounding.

### 3.3. Lean–rich cycling test

To further evaluate the reduction activity of adsorbed NO<sub>x</sub>, a lean–rich cycling test was carried out over fresh Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> at 550 °C (Fig. 6). During lean periods, NO was first oxidized to NO<sub>2</sub> by Pt; NO<sub>2</sub> was then adsorbed on K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub> support. During rich periods, the adsorbed NO<sub>x</sub> reacted with reducing reagent (H<sub>2</sub>) in the presence of Pt. Because of the high reducing activity of Pt, the main products were N<sub>2</sub> and H<sub>2</sub>O; almost no N<sub>2</sub>O was observed during rich cycles (Fig. 6(B)). Overall, more than 65% of NO<sub>x</sub> was removed during the lean–rich cycling tests.

We also investigated the effect of O<sub>2</sub> concentration on the NO<sub>x</sub> storage and reduction performance (Fig. 7). When H<sub>2</sub> concentration is low (3.5%), the NO<sub>x</sub> storage capacity slightly decreased by increasing O<sub>2</sub> concentration from 4.5% to 10% (see Fig. 7(A)). This might reflect the consumption of H<sub>2</sub> by the slipped O<sub>2</sub> when switching from lean to rich conditions. With higher H<sub>2</sub> concentration (5%), little effect was observed on NO<sub>x</sub> removal within the range of 4.5–10% O<sub>2</sub> (see Fig. 7(B)).

### 3.4. Thermal stability of Pt/K<sub>2</sub>Ti<sub>2</sub>O<sub>5</sub>

The thermal stability is a key problem for conventional NSR catalysts, especially for K-doped type. At high temperature, K will

**Fig. 7.** Effect of  $O_2$  on  $NO_x$  storage and reduction during lean-rich cycling tests over fresh 2 wt.%  $Pt/K_2Ti_2O_5$  in the presence of (A) 3.5%  $H_2$ , or (B) 5%  $H_2$ .

either react with the support or evaporate. For  $Pt/K_2Ti_2O_5$ , since K has already reacted with  $TiO_2$  (in form of  $K_2Ti_2O_5$ ), a higher thermal stability is expected. To prove this,  $Pt/K_2Ti_2O_5$  was pre-treated in oxidative condition (10%  $O_2$ ) at 700 °C for 70 h or 200 h. The  $NO_x$  storage capacities of fresh and oxidative aged  $Pt/K_2Ti_2O_5$  were then evaluated by temperature-programmed adsorptions with  $NO + O_2$ . No clear activity loss was observed even after 200 h treatment in the oxidative condition (see Fig. 8), indicating that  $Pt/K_2Ti_2O_5$  had high thermal stability. This feature is unique to  $Pt/K_2Ti_2O_5$  among all other reported NSR catalysts. Its thermal stability in reductive condition (3.5%  $H_2$ ) was also evaluated by pre-treating at 700 °C for 5 h. Fig. 8 shows that its  $NO_x$  storage activity was even increased after reduction. Since we have proved that  $K_2Ti_2O_5$  is structurally stable in reductive condition (see Fig. 1), the enhanced performance of reduced  $Pt/K_2Ti_2O_5$  might be due to the reduction of doped Pt. Després et al. [41] has reported that the reduced Pt showed higher NO oxidation activity.

Lean-rich cycling tests over fresh  $Pt/K_2Ti_2O_5$  and lean and rich fluctuating aged  $Pt/K_2Ti_2O_5$  (denoted as lean-rich aged  $Pt/K_2Ti_2O_5$ ) were also investigated, as shown in Fig. 9. After 4 cycles, the

**Fig. 8.** Temperature-programmed adsorptions of  $NO + O_2$  over fresh  $Pt/K_2Ti_2O_5$ , oxidizing aged  $Pt/K_2Ti_2O_5$  in oxidative condition (10%  $O_2$ ) at 700 °C for 70 h or 200 h, and reducing aged  $Pt/K_2Ti_2O_5$  in reductive condition (3.5%  $H_2$ ) at 700 °C for 5 h, respectively.

**Fig. 9.** Evolutions of effluent  $NO + NO_2$  during lean-rich cycling tests over fresh and lean-rich aged  $Pt/K_2Ti_2O_5$  at 550 °C.

performance of fresh  $Pt/K_2Ti_2O_5$  became stable; and no deactivation occurred within 70 min. Its superior stability was further confirmed by aging the sample in a lean-rich fluctuating condition at 700 °C for 5 h. Comparing to fresh  $Pt/K_2Ti_2O_5$ , a similar  $NO_x$  storage and reduction performance was obtained over the lean-rich aged sample. However, Fig. 10 shows that  $Pt-K/TiO_2$  catalysts have much worse thermal stabilities at 550 °C. The initial performance over both  $Pt-K/TiO_2$  ( $K/Ti = 0.5$ ) and  $Pt-K/TiO_2$  ( $K/Ti = 1$ ) was very good; and almost all of the  $NO_x$  could be converted to  $N_2$ . Nevertheless, their performance decreased rapidly with time, and finally lost most of their activities.

### 3.5. Adsorption site and mechanism

In addition to catalytic performance, gaining an understanding of the adsorption site is a key issue for NSR catalysts. For conventional NSR catalysts such as  $Pt-Ba/\gamma-Al_2O_3$  and  $Pt-K/TiO_2$ ,  $NO_x$  is adsorbed on the doped alkali metal oxides as nitrite or nitrate. Since it is widely accepted that K will lose  $NO_x$  storage capacity after reacting with  $TiO_2$ , people might expect that some K came out from the bulk to surface during the synthesis of  $Pt/K_2Ti_2O_5$ . To eliminate such a doubt, we demonstrated that fresh  $K_2Ti_2O_5$  itself adsorbed  $NO_2$  in the temperature range of 500–600 °C by the temperature-programmed adsorption of  $NO_2$  on pure  $K_2Ti_2O_5$ , as shown in Fig. 11. Its adsorption capacity was also evaluated by the isothermal storage of 700 ppm  $NO_2$  at 550 °C with 1.5 g  $K_2Ti_2O_5$ ; saturation was obtained after 1750 min. Based on calculations, a maximum value of around 1.4 mmol  $NO_x$  per gram of  $K_2Ti_2O_5$  was achieved, similar to the value for fresh  $Pt/K_2Ti_2O_5$  (1.2 mmol/g).

**Fig. 10.** Evolutions of effluent  $NO + NO_2$  during lean-rich cycling tests over fresh 2 wt.%  $Pt-K/TiO_2$  ( $K/Ti = 0.5$ ) and 2 wt.%  $Pt-K/TiO_2$  ( $K/Ti = 1$ ) at 550 °C.

Fig. 11. Temperature-programmed adsorption of  $\text{NO}_x$  over fresh pure  $\text{K}_2\text{Ti}_2\text{O}_5$ .

The  $\text{NO}_x$  adsorption mechanism for  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  is different from that for alkali-doped NSR catalysts, as K had already reacted with  $\text{TiO}_2$  to form potassium dititanate. To understand the exact mechanism, fresh  $\text{K}_2\text{Ti}_2\text{O}_5$  was first treated with  $\text{NO}_2$  at  $550^\circ\text{C}$  for various times; the XRD patterns were then analyzed and compared with that of the fresh sample (Fig. 12). With increasing  $\text{NO}_2$  adsorption time, the structure of  $\text{K}_2\text{Ti}_2\text{O}_5$  gradually transformed to another potassium titanate, similar to  $\text{K}_2\text{Ti}_6\text{O}_{13}$ . For  $\text{NO}_2$ -adsorbed  $\text{K}_2\text{Ti}_2\text{O}_5$  (6 h), the peak at  $11.5^\circ$  was much broader than that of synthesized fresh  $\text{K}_2\text{Ti}_6\text{O}_{13}$ , indicating that the  $\text{K}_2\text{Ti}_6\text{O}_{13}$  particles that formed by adsorbing  $\text{NO}_2$  on  $\text{K}_2\text{Ti}_2\text{O}_5$  were very small.

Peaks at  $23.6$ – $23.8^\circ$ ,  $29.4^\circ$ ,  $32.4^\circ$ ,  $33.6$ – $33.8^\circ$ ,  $41.1^\circ$ , and  $46.6^\circ$  gradually appeared, which indicate that  $\text{KNO}_3$ -like compound (PDF 05-0377) was formed by  $\text{NO}_2$  adsorption. The formation of  $\text{KNO}_3$ -like compound was further confirmed by FT-IR analyses (Fig. 13). A peak at  $1382\text{ cm}^{-1}$  appeared after  $\text{NO}_x$  adsorption, and was assigned as free ionic nitrate [9,34,42,43]. After regenerating the sample at  $550^\circ\text{C}$  with 3.5%  $\text{H}_2$  for 0.5 h, the nitrate peak at  $1382\text{ cm}^{-1}$  disappeared, and its FT-IR pattern was exactly the same as that for fresh  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ , indicating that the adsorbed  $\text{NO}_x$  was reduced by  $\text{H}_2$ .

Fig. 14 shows that the  $\text{NO}_2$ -adsorbed  $\text{K}_2\text{Ti}_2\text{O}_5$  could be regenerated by 3.5%  $\text{H}_2$  during temperature-programmed ramping ( $25$ – $750^\circ\text{C}$ ). After regeneration, the structure transformed back to  $\text{K}_2\text{Ti}_2\text{O}_5$ , indicating that the structure transformation is reversible. All the analyses indicate that  $\text{NO}_2$  was adsorbed on the K sites located in the inter-layers of  $\text{K}_2\text{Ti}_2\text{O}_5$ , thereby consuming a certain

Fig. 12. XRD patterns of fresh  $\text{K}_2\text{Ti}_2\text{O}_5$ ,  $\text{NO}_2$  adsorbed  $\text{K}_2\text{Ti}_2\text{O}_5$  (2 h),  $\text{NO}_2$  adsorbed  $\text{K}_2\text{Ti}_2\text{O}_5$  (6 h), and fresh  $\text{K}_2\text{Ti}_6\text{O}_{13}$ ; (▼)  $\text{KNO}_3$  (PDF 05-0377).

Fig. 13. FTIR of fresh  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ ,  $\text{NO}_x$  adsorbed  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  at  $550^\circ\text{C}$  (3 h) and regenerated  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  at  $550^\circ\text{C}$  (0.5 h).

Fig. 14. XRD patterns of fresh  $\text{K}_2\text{Ti}_2\text{O}_5$  and  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ , and regenerated  $\text{K}_2\text{Ti}_2\text{O}_5$  and  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$ ; (◆) Pt.

amount of potassium. The resulting shortage of potassium meant that  $\text{K}_2\text{Ti}_2\text{O}_5$  transformed to other titanates with lower K/Ti values, such as  $\text{K}_2\text{Ti}_6\text{O}_{13}$ . The  $\text{NO}_x$  storage and reduction performances over  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  were achieved by a reversible structure transformation between  $\text{K}_2\text{Ti}_2\text{O}_5$  and  $\text{K}_2\text{Ti}_6\text{O}_{13}$ .

The  $\text{NO}_x$  storage and reduction mechanism over  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  during lean and rich conditions was proposed as Fig. 15. During lean period,  $\text{NO}$  is first oxidized to  $\text{NO}_2$ , and  $\text{NO}_2$  is then adsorbed on K to form  $\text{KNO}_3$ -like compound. This process is accompanied by a structure change from  $\text{K}_2\text{Ti}_2\text{O}_5$  to  $\text{K}_2\text{Ti}_6\text{O}_{13}$ . During rich period,

Fig. 15. Proposed  $\text{NO}_x$  storage and reduction mechanism over  $\text{Pt}/\text{K}_2\text{Ti}_2\text{O}_5$  in lean and rich conditions.

the adsorbed  $\text{NO}_x$  species will release and react with reductive agent ( $\text{H}_2$ ) in the presence Pt, forming  $\text{N}_2$  and  $\text{H}_2\text{O}$ . In the mean time,  $\text{K}_2\text{Ti}_6\text{O}_{13}$  transforms back to  $\text{K}_2\text{Ti}_2\text{O}_5$  by reacting with the released K.

#### 4. Conclusions

In the present work,  $\text{K}_2\text{Ti}_2\text{O}_5$ , prepared by solid state reaction between  $\text{TiO}_2$  and K, showed  $\text{NO}_x$  adsorption activity at 500–600 °C; on this basis, Pt/ $\text{K}_2\text{Ti}_2\text{O}_5$  obtained by impregnating Pt on  $\text{K}_2\text{Ti}_2\text{O}_5$  was further developed as a high-temperature NSR catalyst. Here,  $\text{K}_2\text{Ti}_2\text{O}_5$  worked as both support and  $\text{NO}_x$  absorber. XRD and SEM–EDX analyses indicated that K has completely reacted with  $\text{TiO}_2$  to form  $\text{K}_2\text{Ti}_2\text{O}_5$ , and no doped K was found in the synthesized samples. The effects of Pt loadings and  $\text{NO}_x$  species were studied by temperature-programmed adsorptions, revealing that the oxidation of NO to  $\text{NO}_2$  is a limiting step of  $\text{NO}_x$  storage for Pt/ $\text{K}_2\text{Ti}_2\text{O}_5$  at high temperatures. TPD results demonstrated high stability ( $T_p \sim 720$  °C) of  $\text{NO}_x$  adsorbed on Pt/ $\text{K}_2\text{Ti}_2\text{O}_5$ . A maximum value of adsorbed  $\text{NO}_x$  close to 1.2 mmol/g catalyst was obtained by isothermal storage at 550 °C, even higher than that of Pt–Ba/ $\gamma$ - $\text{Al}_2\text{O}_3$  (0.8 mmol/g, 350 °C). Lean–rich cycling tests performed at 550 °C revealed that the adsorbed  $\text{NO}_x$  is easily reduced to  $\text{N}_2$  and  $\text{H}_2\text{O}$  by reducing agents (e.g.,  $\text{H}_2$ ); almost no  $\text{N}_2\text{O}$  was observed during rich conditions. Lean–rich cycling operations over fresh and aged Pt/ $\text{K}_2\text{Ti}_2\text{O}_5$  at 550 °C revealed its superior thermal stability; nevertheless, Pt–K/ $\text{TiO}_2$  showed a much worse stability and deactivated rapidly in the same conditions. XRD and FT-IR analyses revealed that  $\text{KNO}_3$ -like compound formed after  $\text{NO}_2$  adsorption on  $\text{K}_2\text{Ti}_2\text{O}_5$ ; consumption of K meant that  $\text{K}_2\text{Ti}_2\text{O}_5$  transformed to other types of potassium titanate (most likely  $\text{K}_2\text{Ti}_6\text{O}_{13}$ ). After regenerating the  $\text{NO}_x$ -adsorbed  $\text{K}_2\text{Ti}_2\text{O}_5$  by  $\text{H}_2$  during temperature-programmed ramping (25–750 °C), the sample transformed back to  $\text{K}_2\text{Ti}_2\text{O}_5$ , indicating that the structure transformation is reversible. Considering its high  $\text{NO}_x$  storage capacity and good thermal stability, Pt/ $\text{K}_2\text{Ti}_2\text{O}_5$  is potential for practical application as a high-temperature NSR catalyst.
